## **CourseMaterial**

**Paper Name:DATABASE SYSTEMS**

**Paper code:16SCCCA4**

**Staff name:K.ANITHA M.CA.,MPhil**

**No of units:5 units**

**DATABASESYSTEMS****UnitI**

Introduction:Database-SystemApplications-PurposeofDatabaseSystems-Viewof Data--DatabaseLanguages-RelationalDatabases-DatabaseDesign-Object-BasedandSemistructured Databases-DataStorage andQueryingTransactionManagement- DataMiningand Analysis - Database Architecture - Database Users and Administrators - History ofDatabaseSystems.

**UnitII**

Relational Model: Structure of Relational Databases - Fundamental Relational-AlgebraOperations Additional Relational-Algebra Operations- Extended Relational-AlgebraOperations-Null Values-Modification ofthe Database.

**UnitIII**

SQL: Data Definition - Basic Structure of SQL Queries - Set Operations - AggregateFunctions - NullValues- Nested Subqueries-ComplexQueries-Views - Modification of the Database - Joined Relations - SQL Data Types and Schemas - IntegrityConstraints-Authorization-Embedded SQL

**UnitIV**

RelationalLanguages:The TupleRelational Calculus-The DomainRelational Calculus -Query-by- Example. Database Design and the E-R Model: Overview of the Design Process - The Entity-Relationship Model - 3 Constraints - Entity-Relationship Diagrams - Entity-Relationship Design Issues - Weak Entity Sets - Database Design for Banking Enterprise  
**Unit V**

Relational Database Design: Features of Good Relational Designs - Atomic Domains andFirst Normal Form - Decomposition Using Functional Dependencies - Functional- DependencyTheory - Decomposition Using Functional Dependencies - Decomposition Using MultivaluedDependencies-MoreNormal Forms-Database-Design Process

**TextBook:**

1. Database System Concepts, Fifth edition, Abraham Silberschatz , Henry F. Korth, S.Sudarshan,McGraw-Hill-2005.

**Unit-1****DatabaseManagementSystem(DBMS)**

- DBMS containsinformationaboutaparticularenterprise
  - Collectionofinterrelated data
  - Setofprogramstoaccessthe data
  - Anenvironmentthatisboth *convenient*and*efficient*to use

- Database Applications:
  - Banking: all transactions
  - Airlines: reservations, schedules
  - Universities: registration, grades
  - Sales: customers, products, purchases
  - Onlineretailers: order tracking, customized recommendations
  - Manufacturing: production, inventory, orders, supply chain
  - Humanresources: employee records, salaries, tax deductions
- Databases touch all aspects of our lives

## Purpose of Database Systems

- In the early days, database applications were built directly on top of filesystems
- Drawbacks of using filesystems to store data:
  - Data redundancy and inconsistency
    - Multiple file formats, duplication of information in different files
  - Difficulty in accessing data
    - Need to write a new program to carry out each new task
  - Data isolation — multiple files and formats
  - Integrity problems
    - Integrity constraints (e.g. account balance > 0) become “buried” in program code rather than being stated explicitly
    - Hard to add new constraints or change existing ones
  - Atomicity of updates
    - Failures may leave database in an inconsistent state with partial updates carried out
    - Example: Transfer of funds from one account to another should either complete or not happen at all
  - Concurrent access by multiple users
    - Concurrent access needed for performance
    - Uncontrolled concurrent accesses can lead to inconsistencies
      - Example: Two people reading a balance and updating it at the same time
  - Security problems
    - Hard to provide user access to some, but not all, data

Database systems offer solutions to all the above problems

## Levels of Abstraction

- Physical level: describes how a record (e.g., customer) is stored.
- Logical level: describes data stored in database, and the relationships among the data. type *customer* = record

```

customer_id :  

string;customer_name :  

string;customer_street :  

string;customer_city:integer  

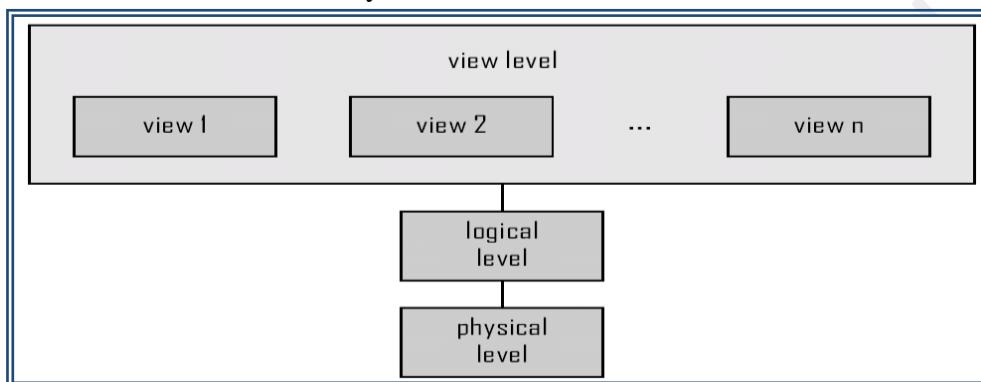

end; ;

```

- View level: application programs hide details of data types. Views can also hide information (such as an employee's salary) for security purposes.

## View of Data

An architecture for a database system

Instances and Schemas

- Similar to types and variables in programming languages
- Schema – the logical structure of the database
  - Example: The database consists of information about a set of customers and accounts and the relationship between them)
  - Analogous to type information of a variable in a program
  - Physical schema: database design at the physical level
  - Logical schema: database design at the logical level
- Instance – the actual content of the database at a particular point in time
  - Analogous to the value of a variable
- Physical Data Independence –
  - the ability to modify the physical schema without changing the logical schema
  - Applications depend on the logical schema
  - In general, the interfaces between the various levels and components should be well defined so that changes in some parts do not seriously influence others.

## Data Models

- A collection of tools for describing
  - Data
  - Data relationships
  - Data semantics

- Dataconstraints
- Relationalmodel
- Entity-Relationshipdatamodel(mainlyfordatabasedesign)
- Object-baseddatamodels(Object-orientedandObject-relational)
- Semistructureddatamodel(XML)
- Otheroldermodels:
  - Networkmodel
  - Hierarchicalmodel

### **DataManipulationLanguage(DML)**

- Language foraccessingand manipulatingthedataorganized bythe appropriatedatamodel
  - DMLalso known as querylanguage
- Twoclassesoflanguages
  - Procedural –userspecifies whatdatais requiredandhowto getthosedata
  - Declarative(nonprocedural)–userspecifies what dataisrequiredwithoutspecifyinghow to get thosedata
- SQListthemostwidelyusedquerylanguage

### **DataDefinitionLanguage(DDL)**

- SpecificationnotationfordefiningthedatabaseschemaExample: createtable *account* (
 

<i>account-number</i>	char(10),
<i>balance</i>	integer)
- DDLcompilergeneratesasetoftablesstored inadatadictionary
- Datadictionarycontainsmetadata(i.e.,dataaboutdata)
  - Databaseschema
  - Datastorageanddefinitionlanguage
    - Speciesthestoragestructureandaccessmethodsused
  - Integrityconstraints
    - Domainconstraints
    - Referentialintegrity(referencesconstraintinSQL)
    - Assertions
  - Authorization

### **RelationalModel**

<i>customer_id</i>	<i>customer_name</i>	<i>customer_street</i>	<i>customer_city</i>	<i>account_number</i>
192-83-7465	Johnson	12 Alma St.	Palo Alto	A-101
192-83-7465	Johnson	12 Alma St.	Palo Alto	A-201
677-89-9011	Hayes	3 Main St.	Harrison	A-102
182-73-6091	Turner	123 Putnam St.	Stamford	A-305
321-12-3123	Jones	100 Main St.	Harrison	A-217
336-66-9999	Lindsay	175 Park Ave.	Pittsfield	A-222
019-28-3746	Smith	72 North St.	Rye	A-201

SQL

- SQL: widely used non-procedural language
  - Example: Find the name of the customer with customer-id 192-83-7465
 

```
select customer.customer_name
from customer
where customer.customer_id='192-83-7465'
```
  - Example: Find the balances of all accounts held by the customer with customer-id 192-83-7465
 

```
select account.balance
from depositor, account
where depositor.customer_id='192-83-7465' and
depositor.account_number=account.account_number
```
- Application programs generally access databases through one of
  - Language extensions to allow embedded SQL
  - Application program interface (e.g., ODBC/JDBC) which allow SQL queries to be sent to a database

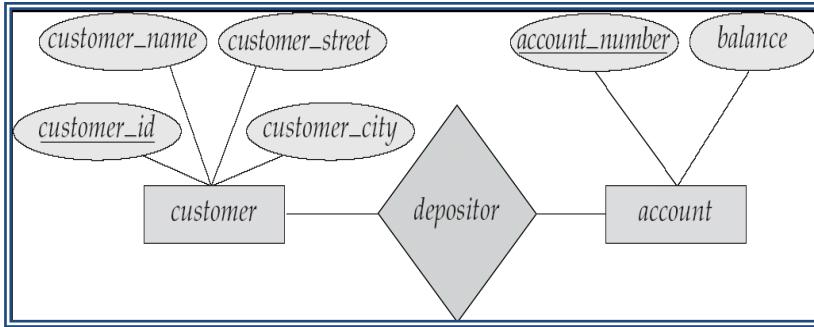

## Database Design

The process of designing the general structure of the database:

- Logical Design – Deciding on the database schema. Database design requires that we find a “good” collection of relation schemas.
  - Business decision – What attributes should be recorded in the database?
  - Computer Science decision – What relation schemas should we have and how should the attributes be distributed among the various relation schemas?
- Physical Design – Deciding on the physical layout of the database

## The Entity-Relationship Model

- Models an enterprise as a collection of *entities* and *relationships*
  - Entity: a “thing” or “object” in the enterprise that is distinguishable from other objects
    - Described by a set of *attributes*
  - Relationship: an association among several entities
- Represented diagrammatically by an *entity-relationship diagram*:
-

### Object-RelationalDataModels

- Extend the relational data model by including object orientation and constructs to deal with added data types.
- Allow attributes of tuples to have complex types, including non-atomic values such as nested relations.
- Preserve relational foundations, in particular the declarative access to data, while extending modeling power.
- Provide upward compatibility with existing relational

languages.

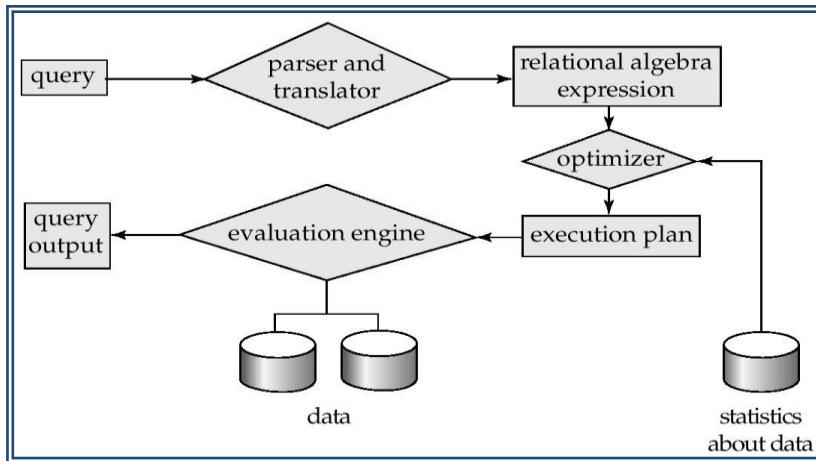

- XML: Extensible Markup Language**
- Defined by the WWW Consortium (W3C)
  - Originally intended as a document markup language not a database language
  - The ability to specify new tags, and to create nested tag structures made XML a great way to exchange data, not just documents
  - XML has become the basis for all new generation data interchange formats.
  - A wide variety of tools is available for parsing, browsing and querying XML documents/data

### StorageManagement

- Storage manager is a program module that provides the interface between the low-level data stored in the database and the application programs and queries submitted to the system.
- The storage manager is responsible to the following tasks:
  - Interaction with the file manager
  - Efficient storing, retrieving and updating of data
- Issues:
  - Storage access
  - File organization
  - Indexing and hashing

### QueryProcessing

1. Parsing and translation
2. Optimization
3. Evaluation

- Alternative ways of evaluating a given query
  - Equivalent expressions
  - Different algorithms for each operation
- Cost difference between a good and a bad way of evaluating a query can be enormous
- Need to estimate the cost of operations
  - Depends critically on statistical information about relations which the database must maintain
  - Need to estimate statistics for intermediate results to compute cost of complex expressions

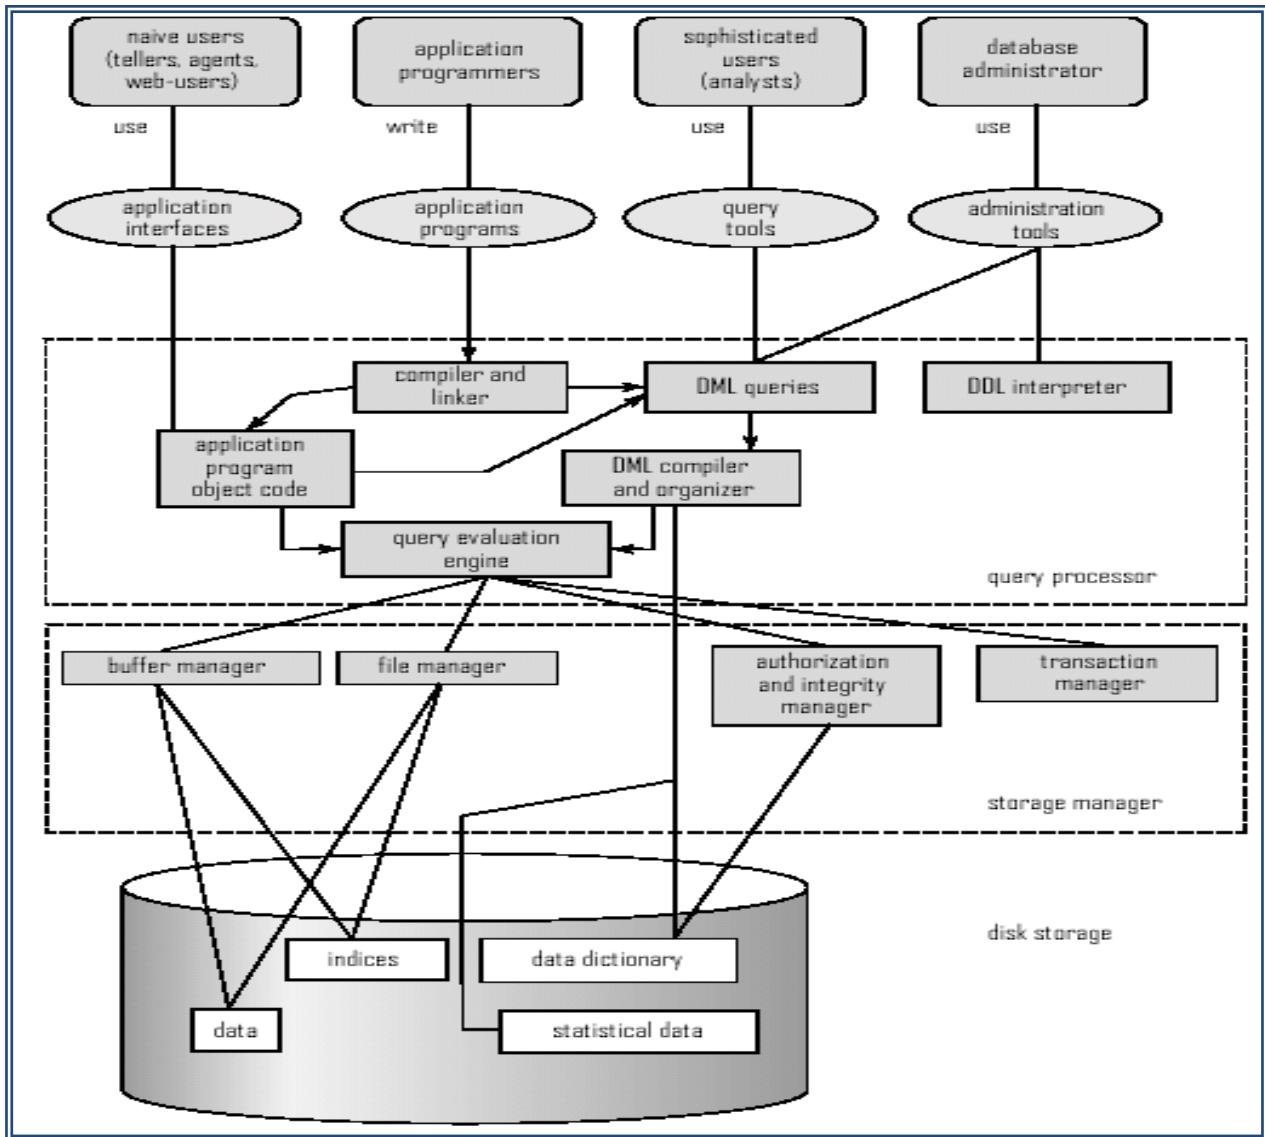

## Transaction Management

- A transaction is a collection of operations that performs a single logical function in a database application
- Transaction-management component ensures that the database remains in a consistent (correct) state despite system failures (e.g., power failures and operating system crashes) and transaction failures.
- Concurrency-control manager controls the interaction among the concurrent transactions, to ensure the consistency of the database.

## Database Architecture

The architecture of a database system is greatly influenced by the underlying computer system on which the database is running:

- Centralized
- Client-server
- Parallel (multi-processor)
- Distributed

## DatabaseUsers

Users are differentiated by the way they expect to interact with the system

- Application programmers – interact with system through DML calls
- Sophisticated users – form requests in a database query language
- Specialized users – write specialized database applications that do not fit into the traditional data processing framework
- Naïve users – invoke one of the permanent application programs that have been written previously
  - Examples, people accessing database over the web, bank tellers, clerical staff

## DatabaseAdministrator

- Coordinates all the activities of the database system; the database administrator has a good understanding of the enterprise's information resources and needs.
- Database administrator's duties include:

- Schema definition
- Storage structure and access method definition
- Schema and physical organization modification
- Granting user authority to access the database
- Specifying integrity constraints
- Acting as liaison with users
- Monitoring performance and responding to changes in requirements

### **History of Database Systems**

- 1950s and early 1960s:
  - Data processing using magnetic tapes for storage
    - Tapes provide only sequential access
  - Punched cards for input
- Late 1960s and 1970s:
  - Hard disks allow direct access to data
  - Network and hierarchical data models in widespread use
  - Ted Codd defines the relational data model
    - Would win the ACM Turing Award for this work
    - IBM Research begins System R prototype
    - UC Berkeley begins Ingres prototype
  - High-performance (for the era) transaction processing
- 1980s:
  - Research relational prototypes evolve into commercial systems
    - SQL becomes industrial standard
  - Parallel and distributed database systems
  - Object-oriented database systems
- 1990s:
  - Large decision support and data-mining applications
  - Large multi-terabyte data warehouses
  - Emergence of Web commerce
- 2000s:
  - XML and XQuery standards
  - Automated database administration

# Unit-2

## Relational Model

- Structure of Relational Databases
- Fundamental Relational Algebra Operations
- Additional Relational Algebra Operations
- Extended Relational Algebra Operations
- Null Values
- Modification of the Database

## Basic Structure

- Formally, given sets  $D_1, D_2, \dots, D_n$  are relations  $r$  is a subset of  $D_1 \times D_2 \times \dots \times D_n$

Thus, a relation is a set of  $n$ -tuples  $(a_1, a_2, \dots, a_n)$  where each  $a_i \in D_i$

- Example: If
  - $customer\_name = \{Jones, Smith, Curry, Lindsay, \dots\}$   
/\* Set of all customer names \*/
  - $customer\_street = \{Main, North, Park, \dots\}$  /\* Set of all street names \*/
  - $customer\_city = \{Harrison, Rye, Pittsfield, \dots\}$  /\* Set of all city names \*/

\* Then  $r = \{(Jones, Main, Harrison),$   
 $(Smith, North,$   
 $Rye), (Curry, North,$   
 $Rye), (Lindsay, Park, Pittsfield)$   
 $\}$

is a relation over

$customer\_name \times customer\_street \times customer\_city$

## 1. Attribute Types

- Each attribute of a relation has a name
- The set of allowed values for each attribute is called the domain of the attribute
- Attribute values are (normally) required to be atomic; that is, indivisible
  - E.g. the value of an attribute can be an account number, but cannot be a set of account numbers
- Domain is said to be atomic if all its members are atomic
- The special value *null* is a member of every domain
- The *null* value causes complications in the definition of many operations
  - We shall ignore the effect of *null* values in our main presentation and consider them effects later

## 2. Relation Schema

- $A_1, A_2, \dots, A_n$  are attributes
- $R = (A_1, A_2, \dots, A_n)$  is a relation schema

Example:

$Customer\_schema = (customer\_name, customer\_street, customer\_city)$

- $r(R)$  denotes a relation  $r$  on the relation schema  $R$

Example:

*customer(Customer\_schema)*

### 3.RelationInstance

- The current values (*relation instance*) of a relation are specified by a table
- An element  $t$  of  $r$  is a *tuple*, represented by a *row* in a table

Relations are Unordered

- n Order of tuples is irrelevant (tuples may be stored in an arbitrary order)

Example: *account* relation with unordered tuples

account_number	branch_name	balance
A-101	Downtown	500
A-215	Mianus	700
A-102	Perryridge	400
A-305	Round Hill	350
A-201	Brighton	900
A-222	Redwood	700
A-217	Brighton	750

### Database

- A database consists of multiple relations
- Information about an enterprise is broken up into parts, with each relation storing one part of the information

*account*: stores information about accounts

*depositor* : stores information about which customer owns which account

*customer*: stores information about customers

- Storing all information as single relations such as

*bank(account\_number, balance, customer\_name, ..)* results in

- repetition of information

- e.g., if two customers own an account (What gets repeated?)

- the need for null values

- e.g., to represent a customer without an account

- Normalization theory (Chapter 7) deals with how to design relational schemas

The *customer* Relation

<i>customer_name</i>	<i>customer_street</i>	<i>customer_city</i>
Adams	Spring	Pittsfield
Brooks	Senator	Brooklyn
Curry	North	Rye
Glenn	Sand Hill	Woodside
Green	Walnut	Stamford
Hayes	Main	Harrison
Johnson	Alma	Palo Alto
Jones	Main	Harrison
Lindsay	Park	Pittsfield
Smith	North	Rye
Turner	Putnam	Stamford
Williams	Nassau	Princeton

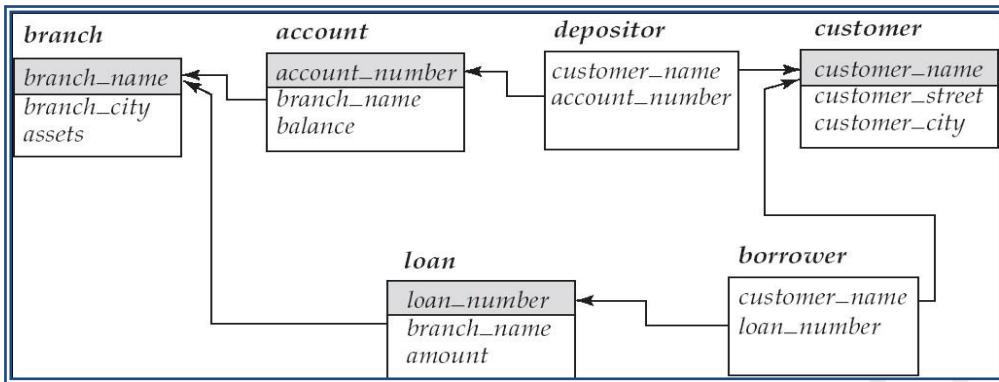

#### 4.Keys

- Let  $K \subseteq R$
- $K$  is a superkey of  $R$  if values for  $K$  are sufficient to identify a unique tuple of each possible relation  $r(R)$ 
  - by “possible  $r$ ” we mean a relation  $r$  that could exist in the enterprise we are modeling.
  - Example:  $\{customer\_name, customer\_street\}$  and  $\{customer\_name\}$  are both superkeys of *Customer*, if no two customers can possibly have the same name
    - In real life, an attribute such as *customer\_id* would be used instead of *customer\_name* to uniquely identify customers, but we omit it to keep our example small, and instead assume customer names are unique.
- $K$  is a candidate key if  $K$  is minimal  
Example:  $\{customer\_name\}$  is a candidate key for *Customer*, since it is a superkey and no subset of it is a superkey.
- Primary key: a candidate key chosen as the principal means of identifying tuples within a relation
  - Should choose an attribute whose value never, or very rarely, changes.
  - E.g. email address is unique, but may change

#### 5.Foreign Keys

- A relation schema may have an attribute that corresponds to the primary key of another relation. The attribute is called a foreign key.
  - E.g. *customer\_name* and *account\_number* attributes of *depositor* are foreign keys to *customer* and *account* respectively.

- Only values occurring in the primary key attribute of the referenced relation may occur in the foreign key attribute of the referencing relation.
- Schema diagram

## 6.Query Languages

- Language in which user requests information from the database.
- Categories of languages
  - Procedural
  - Non-procedural, or declarative
- “Pure” languages:
  - Relational algebra
  - Tuple relational calculus
  - Domain relational calculus
- Pure languages form underlying basis of query languages that people use.

## Fundamental Relational Algebra

- Procedural language
- Six basic operators
  - select:  $\sigma$
  - project:  $\Pi$
  - union:  $\cup$
  - set difference:  $-$
  - Cartesian product:  $\times$
  - rename:  $\rho$
- The operators take one or two relations as inputs and produce a new relation as a result.

### SelectOperation

- Notation:  $\sigma_p(r)$
- $p$  is called the selection predicate
- Defined as:

$$\sigma_p(r) = \{t | t \in r \text{ and } p(t)\}$$

Where  $p$  is a formula in propositional calculus consisting of terms connected by:  $\wedge$ (and),  $\vee$ (or),  $\neg$ (not)

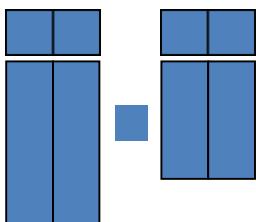

Each term is one of:

<attribute>  $op$  <attribute> or

<constant> where  $op$  is one of:  $=, \neq, >, \geq, <, \leq$

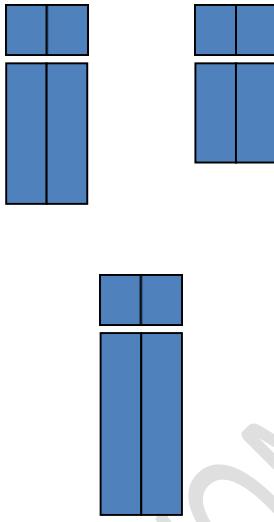

- Example of selection:

$$\sigma_{branch\_name = "Perryridge"}(account)$$

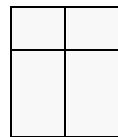

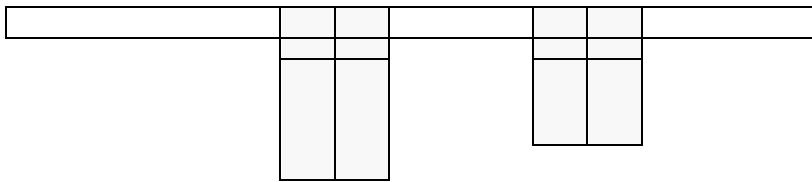

- Notation:  
where  $A_1, A_2$  are attribute names and  $r$  is a relation name.
- The result is defined as the relation of  $k$  columns obtained by erasing the columns that are not listed
- Duplicate rows removed from result, since relations are sets
- Example: To eliminate the  $branch\_name$  attribute of  $account$

$$\Pi_{account\_number, balance}(account)$$

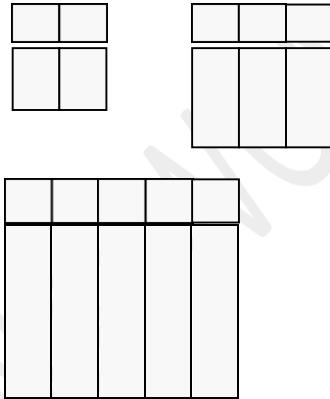

- Notation:  $r \cup s$
  - Defined as:
- $$r \cup s = \{t | t \in r \text{ or } t \in s\}$$
- For  $r \cup s$  to be valid.
    - $r, s$  must have the same arity (same number of attributes)
    - The attribute domains must be compatible (example: 2<sup>nd</sup> column of  $r$  deals with the same type of values as does the 2<sup>nd</sup> column of  $s$ )
  - Example: to find all customers who either have an account or a loan

$$\Pi_{customer\_name}(depositor) \cup \Pi_{customer\_name}(borrower)$$

- Notation  $r - s$
- Defined as:  

$$r - s = \{t | t \in r \text{ and } t \notin s\}$$
- Set differences must be taken between compatible relations.
  - $r$  and  $s$  must have the same arity
  - attributed domains of  $r$  and  $s$  must be compatible

- Notation  $r \times s$
- Defined as:  

$$r \times s = \{t q | t \in r \text{ and } q \in s\}$$
- Assume that attributes of  $r(R)$  and  $s(S)$  are disjoint. (That is,  $R \cap S = \emptyset$ ).
- If attributes of  $r(R)$  and  $s(S)$  are not disjoint, then renaming must be used. Composition of Operations
  - Can build expressions using multiple operations
  - Example:  $\sigma_{A=C}(r \times s)$
  - $r \times s$
  - $\sigma_{A=C}(r \times s)$

### RenameOperation

- Allows us to name, and therefore refer to, the results of relational-algebra expressions.
- Allows us to refer to a relation by more than one name.
- Example:

$$\rho_x(E)$$

returns the expression  $E$  under the name  $X$

- If a relational-algebra expression  $E$  has arity  $n$ , then

returns the result of expression  $E$  under the name  $X$ , and with the attributes renamed to  $A_1, A_2, \dots, A_n$ .

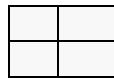

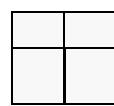

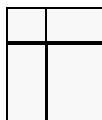

### AdditionalRelationalalgebraOperations

We define additional operations that do not add any power to the relational algebra, but that simplify common queries.

- Set intersection
- Natural join
- Division
- Assignment

### Set-IntersectionOperation

- Notation:  $r \cap s$
- Defined as:
- $r \cap s = \{ t | t \in r \text{ and } t \in s \}$
- Assume:
  - $r, s$  have the same arity
  - attributes of  $r$  and  $s$  are compatible
- Note:  $r \cap s = r - (r - s)$

## Natural-Join Operation

- Let  $r$  and  $s$  be relations on schemas  $R$  and  $S$  respectively.
- Then,  $r \bowtie s$  is a relation on schema  $R \cup S$  obtained as follows:
  - Consider each pair of tuples  $t_r$  from  $r$  and  $t_s$  from  $s$ .
  - If  $t_r$  and  $t_s$  have the same value on each of the attributes in  $R \cap S$ , add a tuple  $t$  to the result, where
    - $t$  has the same value as  $t_r$  on  $R$
    - $t$  has the same value as  $t_s$  on  $S$
- Example:

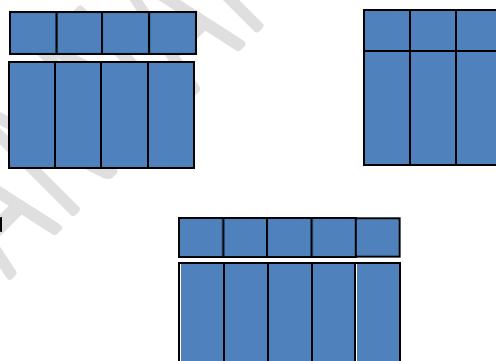

$$R = (A, B, C)$$

$$D)S = (E, B, D)$$

- Resultschema  $= (A, B, C, D, E)$

- $r \bowtie s$  is defined as:

$$\prod_{r.A=r.B=r.C=r.D,s.E} (\sigma_{r.B=s.B \wedge r.D=s.D}(r \bowtie s))$$

## Division Operation

- Notation:
- Suited to queries that include the phrase “forall”.
- Let  $r$  and  $s$  be relations on schemas  $R$  and  $S$  respectively where

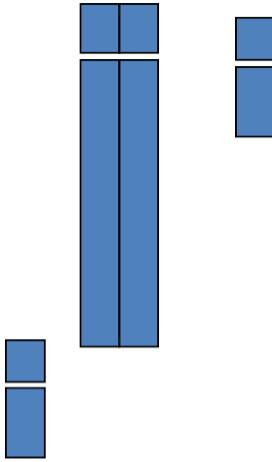

- $R = (A_1, \dots, A_m, B_1, \dots, B_n)$
- $S = (B_1, \dots, B_n)$

The result of  $r \div s$  is a relation on schema

$$R - S = (A_1, \dots, A_m)$$

$$r \div s = \{ t | t \in \prod_{R-S}(r) \wedge \forall u \in s (tu \in r) \}$$

Where  $tu$  means the concatenation of tuple  $t$  and  $u$  to produce a single tuple

- Property
  - Let  $q = r \div s$
  - Then  $q$  is the largest relation satisfying  $q \times s \subseteq r$
- Definition in terms of the basic algebra operation Let  $r(R)$  and  $s(S)$  be relations, and let  $S \subseteq R$ 

$$r \div s = \prod_{R-S}(r) - \prod_{R-S}((\prod_{R-S}(r) \times s) - \prod_{R-S,S}(r))$$

To see why

  - $\prod_{R-S,S}(r)$  simply reorders attributes of  $r$
  - $\prod_{R-S}(\prod_{R-S}(r) \times s) - \prod_{R-S,S}(r)$  gives those tuples in

$\prod_{R-S}(r)$  such that for some tuple  $u \in s, tu \notin r$ .

### Assignment Operation

- The assignment operation ( $\leftarrow$ ) provides a convenient way to express complex queries.
  - Write query as a sequential program consisting of
    - a series of assignments
    - followed by an expression whose value is displayed as a result of the query.
  - Assignment must always be made to a temporary relation variable.
- Example: Write  $r \div s$  as

```

$$\begin{aligned} temp1 &\leftarrow \Pi_{R-S}(r) \\ temp2 &\leftarrow \Pi_{R-S}((temp1 \times s) - \Pi_{R-S,S}(r)) \\ result &= temp1 - temp2 \end{aligned}$$

```

- The result to the right of the  $\leftarrow$  is assigned to the relation variable on the left of the  $\leftarrow$ .
- May use variable in subsequent expressions.

### Extended Relational Algebra Operations

- Generalized Projection
- Aggregate Functions
- Outer Join

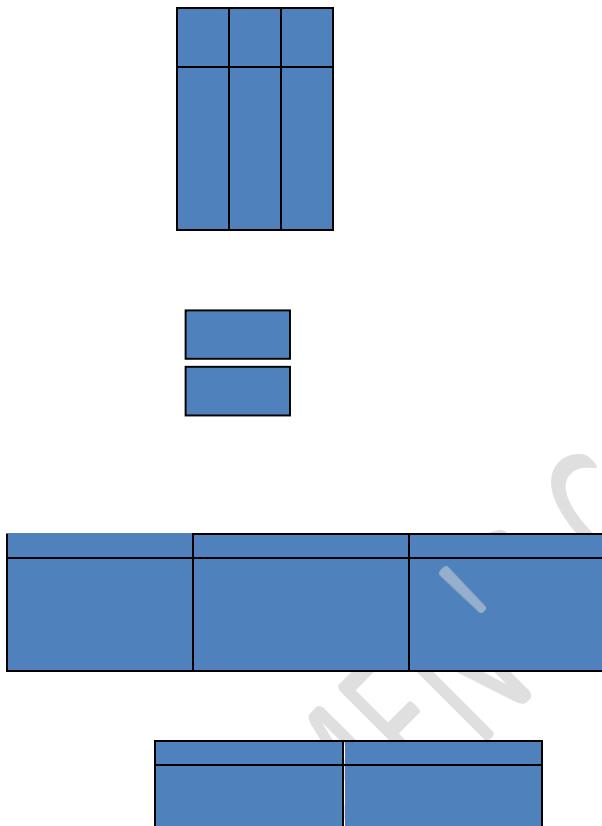

#### Generalized Projection

- Extends the projection operation by allowing arithmetic functions to be used in the projection list.
- $E$  is any relational-algebra expression
- Each of  $F_1, F_2, \dots, F_n$  are arithmetic expressions involving constants and attributes in the schema of  $E$ .
- Given relation  $credit\_info(customer\_name, limit, credit\_balance)$ , find how much more each person can spend:

$$\Pi_{customer\_name, limit - credit\_balance}(credit\_info)$$

#### Aggregate Functions and Operations

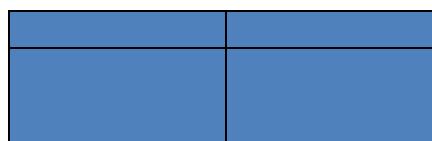

- Aggregation function takes a collection of values and returns a single value as a result.
  - avg: average value
  - min: minimum
  - max: maximum
  - sum: sum of
  - count: number of values
- Aggregate operation in relational algebra
- $E$  is any relational-algebra expression
  - $G_1, G_2, \dots, G_n$  is a list of attributes on which to group (can be empty)
  - Each  $F_i$  is an aggregate function
  - Each  $A_i$  is an attribute name

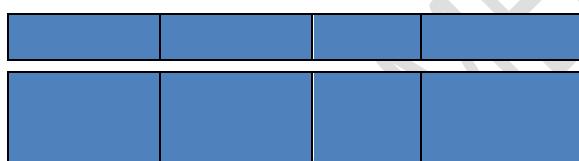

- Result of aggregation does not have a name
  - Can use `rename` operation to give it a name
  - For convenience, we permit renaming as part of aggregate operation

### OuterJoin

- An extension of the join operation that avoids loss of information.
- Computes the join and then adds tuples from one relation that does not match tuples in the other relation to the result of the join.
- Uses `null` values:
  - `null` signifies that the value is unknown or does not exist
  - All comparisons involving `null` are (roughly speaking) false by definition.
    - We shall study precise meaning of comparisons with nulls later

X

X

▷

▷▷

## NullValues

- It is possible for tuples to have a null value, denoted by *null*, for some of their attributes
- *null* signifies an unknown value or that a value does not exist.
- The result of any arithmetic expression involving *null* is *null*.
- Aggregate functions simply ignore null values (as in SQL)
- For duplicate elimination and grouping, null is treated like any other value, and two nulls are assumed to be the same (as in SQL)
- Comparisons with null values return the special truth value: *unknown*
  - If *false* was used instead of *unknown*, then  $\text{not}(A < 5)$  would not be equivalent to  $A \geq 5$
- Three-valued logic using the truth value *unknown*:
  - OR:  $(\text{unknown} \text{ or } \text{true}) = \text{true}$ ,  $(\text{unknown} \text{ or } \text{false}) = \text{unknown}$ ,  $(\text{unknown} \text{ or } \text{unknown}) = \text{unknown}$
  - AND:  $(\text{true} \text{ and } \text{unknown}) = \text{unknown}$ ,  $(\text{false} \text{ and } \text{unknown}) = \text{false}$ ,  $(\text{false} \text{ and } \text{unknown}) = \text{unknown}$
  - NOT:  $(\text{not } \text{unknown}) = \text{unknown}$
  - In SQL “*P* is unknown” evaluates to true if predicate *P* evaluates to *unknown*
- Result of select predicate is treated as *false* if it evaluates to *unknown*

## Modification of the Database

- The content of the database may be modified using the following operations:
  - Deletion
  - Insertion
  - Updating
- All these operations are expressed using the assignment operator.

## Deletion

- A delete request is expressed similarly to a query, except instead of displaying tuples to the user, the selected tuples are removed from the database.
- Can delete only whole tuples; cannot delete values or only particular attributes
- A deletion is expressed in relational algebra by:

$$r \leftarrow r - E$$

where  $r$  is a relation and  $E$  is a relational algebra query.

### Insertion

- To insert data into a relation, we either:
  - specify a tuple to be inserted
  - write a query whose result is a set of tuples to be inserted
- In relational algebra, an insertion is expressed by:

$$r \leftarrow r \cup E$$

where  $r$  is a relation and  $E$  is a relational algebra expression.

- The insertion of a single tuple is expressed by letting  $E$  be a constant relation containing one tuple.

### Updating

- A mechanism to change a value in a tuple without changing all values in the tuple
- Use the generalized projection operator to do this task
- Each  $F_i$  is either
  - the  $i^{\text{th}}$  attribute of  $r$ , if the  $i^{\text{th}}$  attribute is not updated, or,
  - if the attribute is to be updated  $F_i$  is an expression, involving only constants and the attributes of  $r$ , which gives the new value for the attribute

# Unit3

SQL(structurequerylanguage)

## DataDefinitionLanguage

Allows the specification of not only a set of relations but also information about each relation, including:

- The schema for each relation.
- The domain of values associated with each attribute.
- Integrity constraints
- The set of indices to be maintained for each relation.
- Security and authorization information for each relation.
- The physical storage structure of each relation on disk.

## DomainTypesinSQL

- char(n). Fixed length character string, with user-specified length  $n$ .
- varchar(n). Variable length character strings, with user-specified maximum length  $n$ .
- int. Integer (a finite subset of the integers that is machine-dependent).
- smallint. Small integer (a machine-dependent subset of the integer domain type).
- numeric(p,d). Fixed point number, with user-specified precision of  $p$  digits, with  $n$  digits to the right of decimal point.
- real, double precision. Floating point and double-precision floating point numbers, with machine-dependent precision.
- float(n). Floating point number, with user-specified precision of at least  $n$  digits.
- More are covered in Chapter 4.

## CreateTableConstruct

- An SQL relation is defined using the create table command:

```
create table r (A1D1, A2D2, ..., AnDn,  
    (integrity-constraint1),  
    ...,  
    (integrity-constraintk))
```

  - $r$  is the name of the relation
  - each  $A_i$  is an attribute name in the schema of relation  $r$
  - $D_i$  is the data type of values in the domain of attribute  $A_i$
- Example:

```
create table  
branch(branch_name char(15)  
not null, branch_city  
char(30),  
assets integer)
```

## IntegrityConstraintsinCreateTable

- not null

- $\text{primarykey}(A_1, \dots, A_n)$
- Example: Declare  $\text{branch\_name}$  as the primarykey for  $\text{branch}$
- .
- ```
createtablebranch
        (branch_name      char(15),
         branch_city     char(30),
         assets          integer,pri
                         marykey(branch_name))
```
- primary key declaration on an attribute automatically ensures not null in SQL-92 onwards, needs to be explicitly stated in SQL-89

### **Drop and Alter Table Constructs**

- The drop table command deletes all information about the dropped relation from the database.
- The alter table command is used to add attributes to an existing relation: alter table  $r$  add  $AD$   
where  $A$  is the name of the attribute to be added to relation  $r$  and  $D$  is the domain of  $A$ .
  - All tuples in the relation are assigned  $null$  as the value for the new attribute.
- The alter table command can also be used to drop attributes of a relation: alter table  $r$  drop  $A$   
where  $A$  is the name of an attribute of relation  $r$ 
  - Dropping of attributes not supported by many databases

### **Basic Query Structure**

- SQL is based on set and relational operations with certain modifications and enhancements
- A typical SQL query has the form:

```
select  $A_1, A_2, \dots, A_n$ 
  from  $r_1, r_2, \dots, r_m$ 
    where  $P$ 
      –  $A_i$  represents an attribute
      –  $R_i$  represents a relation
      –  $P$  is a predicate.
```

- This query is equivalent to the relational algebra expression.
- The result of an SQL query is a relation.

### **The select Clause**

- The select clause lists the attributes desired in the result of a query
  - corresponds to the projection operation of the relational algebra

- Example: find the names of all branches in the *loan* relation:  

$$\text{select } branch\_name \\ \text{from } loan$$
- In the relational algebra, the query would be:  

$$\tilde{\Omega}_{branch\_name}(loan)$$
- NOTE: SQL names are case insensitive (i.e., you may use upper- or lower-case letters.)
  - E.g. *Branch\_Name* ≡ *BRANCH\_NAME* ≡ *branch\_name*
  - Some people use uppercase wherever we use bold font.
- SQL allows duplicates in relations as well as in query results.
- To force the elimination of duplicates, insert the keyword *distinct* after *select*.
- Find the names of all branches in the *loan* relation, and remove duplicates select *distinct*  

$$\text{select distinct } branch\_name \\ \text{from } loan$$
- The keyword *all* specifies that duplicates not be removed.  

$$\text{select all } branch\_name \\ \text{from } loan$$
- A asterisk in the *select* clause denotes “all attributes”  

$$\text{select}^* \\ \text{from } loan$$
- The *select* clause can contain arithmetic expressions involving the operation, +, -, \*, and /, and operating on constants or attributes of tuples.
- The query:  

$$\text{select } loan\_number, branch\_name, amount * 100 \\ \text{from } loan$$

would return a relation that is the same as the *loan* relation, except that the value of the attribute *amount* is multiplied by 100.

### The *where* Clause

- The *where* clause specifies conditions that the result must satisfy
  - Corresponds to the selection predicate of the relational algebra.
- To find all loan numbers for loans made at the Perryridge branch with loan amounts greater than \$1200.  

$$\text{select } loan\_number \\ \text{from } loan \\ \text{where } branch\_name = 'Perryridge' \text{ and } amount > 1200$$
- Comparison results can be combined using the logical connectives and, or, and not.
- Comparisons can be applied to results of arithmetic expressions.
- SQL includes a between comparison operator
- Example: Find the loan numbers of those loans with loan amounts between \$90,000 and \$100,000 (that is, <sup>3</sup> \$90,000 and £ \$100,000)

- ```
selectloan_number
      fromloan
      whereamount between 90000 and 100000
```

### The from Clause

- The from clause lists the relations involved in the query
  - Corresponds to the Cartesian product operation of the relational algebra.
- Find the Cartesian product of *borrower* and *loan*

```
select*
  fromborrower,loan
```

Find the name, loan number and loan amount of all customers having a loan at the Perryridge branch.

```
selectcustomer_name, borrower.loan_number, amount
  fromborrower,loan
  whereborrower.loan_number=loan.loan_number and
        branch_name='Perryridge'
```

### The Rename Operation

- The SQL allows renaming relations and attributes using the as clause:
 

```
old-nameasnew-name
```
- Find the name, loan number and loan amount of all customers; rename the column name *loan\_number* as *loan\_id*.
 

```
selectcustomer_name,borrower.loan_numberasloan_id,amount
  fromborrower,loan
  whereborrower.loan_number=loan.loan_number
```

### Tuple Variables

- Tuple variables are defined in the from clause via the use of the as clause.
- Find the customer names and their loan numbers for all customers having a loan at some branch.
 

```
selectcustomer_name,T.loan_number,S.amount
      fromborrower asT, loanasS
      whereT.loan_number =S.loan_number
```

n

Find the names of all branches that have greater assets than some branch located in Brooklyn.

```
selectdistinctT.branch_name
  frombranches T,branch asS
  whereT.assets>S.assets andS.branch_city = 'Brooklyn'
```

- n Keyword as is optional and maybe omitted

*borrower* as *T* ≡ *borrower* *T*

### String Operations

- SQL includes a string-matching operator for comparisons on character strings. The operator “like” uses patterns that are described using two special characters:

- percent(%). The % character matches any substring.
- underscore(\_). The \_ character matches any character.
- Find the names of all customers whose street includes the substring “Main”.
 

```
select customer_name
from customer
where customer_street like '%Main%'
```
- Match the name “Main%”
 

```
like 'Main%' escape '\'
```
- SQL supports a variety of string operations such as
  - concatenation (using “||”)
  - converting from upper to lower case (and vice versa)
  - finding string length, extracting substrings, etc.

### Ordering the Display of Tuples

- List in alphabetic order the names of all customers having a loan in Perryridge branch
 

```
select distinct customer_name
from borrower, loan
where borrower.loan_number = loan.loan_number and
branch_name = 'Perryridge' order by customer_name
```
- We may specify desc for descending order or asc for ascending order, for each attribute; ascending order is the default.
  - Example: order by customer\_name desc

### Duplicates

- In relations with duplicates, SQL can define how many copies of tuples appear in the result.
- Multiset versions of some of the relational algebra operators – given multiset relations  $r_1$  and  $r_2$ :
  1.  $\sigma_\theta(r_1)$ : If there are  $c_1$  copies of tuple  $t_1$  in  $r_1$ , and  $t_1$  satisfies selection  $\sigma_\theta$ , then there are  $c_1$  copies of  $t_1$  in  $\sigma_\theta(r_1)$ .
  2.  $\Pi_A(r)$ : For each copy of tuple  $t_1$  in  $r_1$ , there is a copy of tuple  $\Pi_A(t_1)$  in  $\Pi_A(r_1)$  where  $\Pi_A(t_1)$  denotes the projection of the single tuple  $t_1$ .
  3.  $r_1 \times r_2$ : If there are  $c_1$  copies of tuple  $t_1$  in  $r_1$  and  $c_2$  copies of tuple  $t_2$  in  $r_2$ , there are  $c_1 \times c_2$  copies of the tuple  $t_1, t_2$  in  $r_1 \times r_2$
- Example: Suppose multiset relations  $r_1(A, B)$  and  $r_2(C)$  are as follows:
 
$$r_1 = \{(1, a)(2, a)\} \quad r_2 = \{(2), (3), (3)\}$$
- Then  $\Pi_B(r_1)$  would be  $\{(a), (a)\}$ , while  $\Pi_B(r_1) \times r_2$  would be  $\{(a, 2), (a, 2), (a, 3), (a, 3), (a, 3), (a, 3)\}$
- SQL duplicate semantics:

select  $A_1, A_2, \dots, A_n$   
 from  $r_1, r_2, \dots, r_m$   
 where  $P$   
 is equivalent to the *multiset* version of the expression:

$$\prod_{A_1, A_2, \dots, A_n} (\sigma_P(r_1 \times r_2 \times \dots \times r_m))$$

### SetOperations

- The set operations union, intersect, and except operate on relations and correspond to the relational algebra operations  $\cup, \cap, -$ .
- Each of the above operations automatically eliminates duplicates; to retain all duplicates use the corresponding multiset versions union all, intersect all and except all.

Suppose a tuple occurs  $m$  times in  $r$  and  $n$  times in  $s$ , then, it occurs:

- $m+n$  times in  $r$  union all  $s$
- $\min(m, n)$  times in  $r$  intersect all  $s$
- $\max(0, m-n)$  times in  $r$  except all  $s$
- Find all customers who have a loan, an account, or both:
- (select *customer\_name* from  
 $depositor$ ) union  
 (select *customer\_name* from  $borrower$ )
- Find all customers who have both a loan and an account.
- (select *customer\_name* from  
 $depositor$ ) intersect  
 (select *customer\_name* from  $borrower$ )
- Find all customers who have an account but no loan.
- (select *customer\_name* from  
 $depositor$ ) except  
 (select *customer\_name* from  $borrower$ )

### AggregateFunctions

- These functions operate on the multiset of values of a column of a relation, and return a value
  - avg: average
  - valuemin: minimum
  - valuemax: maximum
  - valuesum: sum of
  - valuescount: number of values
- Find the average account balance at the Perryridge branch.
- select avg (*balance*)  
 from *account*  
 where *branch\_name* = 'Perryridge'
- Find the number of tuples in the *customer* relation.

- `select count(*)  
from customer`
- Find the number of depositors in the bank.
- `select count(distinct customer_name)  
from depositor`

### NullValues

- It is possible for tuples to have a null value, denoted by `null`, for some of their attributes
- `null` signifies an unknown value or that a value does not exist.
- The predicate `is null` can be used to check for null values.
  - Example: Find all loan numbers which appear in the `loan` relation with null values for `amount`.  
`select loan_number  
from loan  
where amount is null`
- The result of any arithmetic expression involving `null` is `null`
  - Example:  $5 + \text{null}$  returns `null`
- However, aggregate functions simply ignore nulls
  - More on next slide

### NullValues and Three Valued Logic

- Any comparison with `null` returns `unknown`
  - Example:  $5 < \text{null} \text{ or } \text{null} < \text{null}$       or     $\text{null} = \text{null}$
- Three-valued logic using the truth value `unknown`:
  - OR:  $(\text{unknown} \text{ or } \text{true}) = \text{true}$ ,  $(\text{unknown} \text{ or } \text{false}) = \text{false}$ ,  $(\text{unknown} \text{ or } \text{unknown}) = \text{unknown}$
  - AND:  $(\text{true} \text{ and } \text{unknown}) = \text{false}$ ,  $(\text{false} \text{ and } \text{unknown}) = \text{false}$ ,  $(\text{unknown} \text{ and } \text{unknown}) = \text{unknown}$
  - NOT:  $(\text{not } \text{unknown}) = \text{unknown}$ 
    - “*P* is unknown” evaluates to true if predicate *P* evaluates to `unknown`
- Result of where clause predicate is treated as `false` if it evaluates to `unknown`

### NullValues and Aggregates

- Total all loan amounts  
`select sum(amount) from loan`
  - Above statement ignores null amounts
  - Result is `null` if there is no non-null amount
- All aggregate operations except `count(*)` ignore tuples with null values on the aggregated attributes.

## **NestedSubqueries**

- SQL provides same mechanism for the nesting of subqueries.
- A subquery is a select-from-where expression that is nested within another query.
- A common use of subqueries is to perform tests for set membership, set comparisons, and set cardinality.

/

## **Views**

- In some cases, it is not desirable for all users to see the entire logical model (that is, all the actual relations stored in the database.)

- Consider a person who needs to know a customer's name, loan number and branch name, but has no need to see the loan amount. This person should see a relation described, in SQL, by

```
(select customer_name,borrower.loan_number,branch_name
      from borrower,loan
      where borrower.loan_number = loan.loan_number)
```

- A view provides a mechanism to hide certain data from the view of certain users.
- Any relation that is not of the conceptual model but is made visible to a user as a "virtual relation" is called a view.
- A view is defined using the create view statement which has the form `create view vname as <queryexpression>` where `<queryexpression>` is any legal SQL expression. The view name is represented by *vname*.
- Once a view is defined, the view name can be used to refer to the virtual relation that the view generates.
- When a view is created, the query expression is stored in the database; the expression is substituted into queries using the view.

### **Modification of the Database – Deletion**

- Delete all account tuples at the Perryridge branch
 

```
delete from account
      where branch_name = 'Perryridge'
```
- Delete all accounts at every branch located in the city 'Needham'.
 

```
delete from account
      where branch_name in (select branch_name
                               from branch
                               where branch_city = 'Needham')
```

### **Modification of the Database – Insertion**

- Add a new tuple to *account*

```
insert into account
           values('A-9732','Perryridge',1200)
```

or equivalently

```
insert into account (branch_name, balance,
                     account_number)
                     values('Perryridge', 1200, 'A-9732')

• Add a new tuple to account with balance set to null

```
insert into account
           values('A-777','Perryridge',null)
```

```

- Provide a gift for all loan customers of the Perryridge branch, a \$200 savings account. Let the loan number serve as the account number for the new savings account inserted into *account*

```

select loan_number, branch_name, 200 from loan
where branch_name = 'Perryridge'
insert into depositor
select customer_name, loan_number
from loan, borrower
where branch_name = 'Perryridge'
and loan.account_number = borrower.account_number

```
- The select from where statement is evaluated fully before any of its results are inserted into the relation (otherwise queries like

```

insert into table1 select * from table1

```

would cause problems)

## Modification of the Database—Updates

- Increase all accounts with balances over \$10,000 by 6%, all other accounts receive 5%.
  - Write two update statements: *update account*

```

set balance = balance * 1.06 where balance > 10000
update account
set balance = balance * 1.05 where balance ≤ 10000

```

  - The order is important
  - Can be done better using the case statement (next slide)

## Joined Relations

- Join operations take two relations and return a result another relation.
- These additional operations are typically used as subquery expressions in the *from* clause
- Join condition— defines which tuples in the two relations match, and what attributes are present in the result of the join.
- Join type— defines how tuples in each relation that do not match any tuple in the other relation (based on the join condition) are treated.

<i>Join types</i>	<i>Join Conditions</i>
<b>inner join</b>	<b>natural</b>
<b>left outer join</b>	<b>on &lt; predicate &gt;</b>
<b>right outer join</b>	<b>using (<math>A_1, A_2, \dots, A_n</math>)</b>
<b>full outer join</b>

## Unit4

### Relational Languages

- Tuple Relational Calculus
- Domain Relational Calculus
- Query-by-Example (QBE)
- Datalog

### Tuple Relational Calculus

- An nonprocedural query language, where each query is of the form  $\{t|P(t)\}$
- It is the set of all tuples  $t$  such that predicate  $P$  is true for  $t$
- $t$  is a tuple variable,  $t[A]$  denotes the value of tuple  $t$  on attribute  $A$
- $t \in r$  denotes that tuple  $t$  is in relation  $r$
- $P$  is a formula similar to that

of the predicate calculus Predicate Calculus Formula

1. Set of attributes and constants
2. Set of comparison operators: (e.g.,  $<$ ,  $\leq$ ,  $=$ ,  $\neq$ ,  $>$ ,  $\geq$ )
3. Set of connectives: and ( $\wedge$ ), or ( $\vee$ ), not ( $\neg$ )
4. Implication ( $\Rightarrow$ ):  $x \Rightarrow y$ , if  $x$  is true, then  $y$  is true

$$x \Rightarrow y \equiv \neg x \vee y$$

5. Set of quantifiers:
  - $\exists t \in r(Q(t))$  ≡ "there exists" a tuple  $t$  in relation  $r$  such that predicate  $Q(t)$  is true
  - $\forall t \in r(Q(t))$  ≡  $Q$  is true "for all" tuples  $t$  in relation  $r$

### Domain Relational Calculus

- An nonprocedural query language equivalent in power to the tuple relational calculus

- Each query is an expression of the form:
 
$$\{ \langle x_1, x_2, \dots, x_n \rangle | P(x_1, x_2, \dots, x_n) \}$$
  - $x_1, x_2, \dots, x_n$  represent domain variables
  - $P$  represents a formula similar to that of the predicate calculus

## Query-by-Example(QBE)

The Result Relation

Ordering the Display of

Tuples Aggregate

Operations Modification of the Database

at a base

## QBE—Basic Structure

A graphical query language which is based (roughly) on the domain relational calculus Two-dimensional syntax—system creates templates of relations that are requested by users Queries are expressed “by example”

## Entity-

### Relationship Model Modeli

ng

A database can be modeled as:

a collection of  
entities, relationships among entities.

An entity is an object that exists and is distinguishable from other objects.

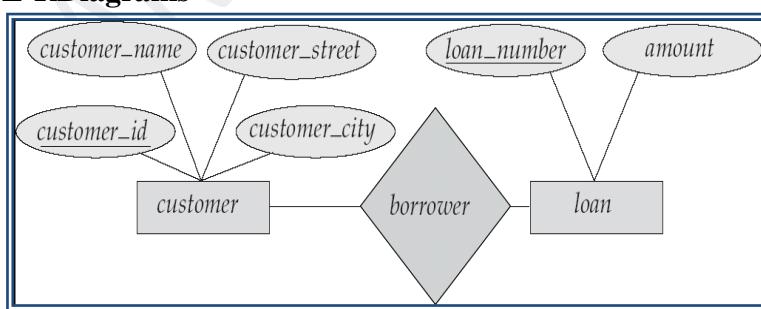

Example: specific person, company, event, plant Entities have attributes

Example: people have names and addresses

An entity set is a set of entities of the same type that share the same properties.

Example: set of all persons, companies, trees, holidays

## E-R Diagrams

Rectangles represent entity sets. Diamonds represent relationships sets.

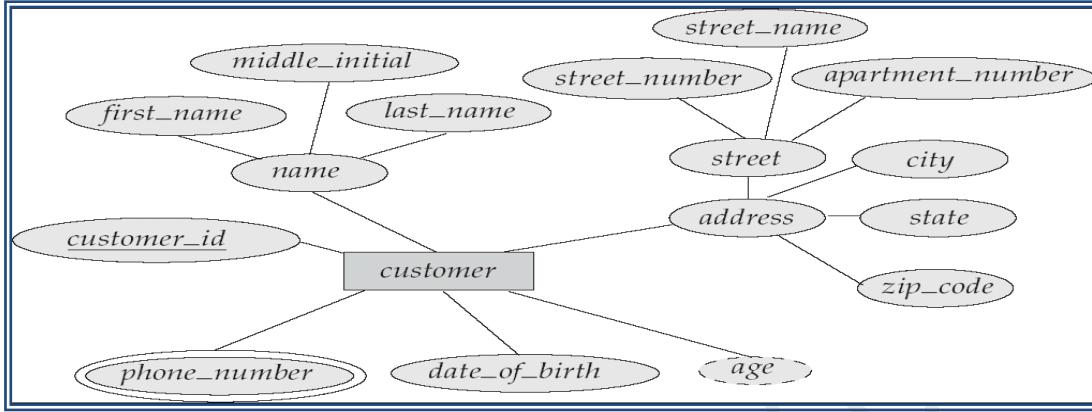

Lines link attributes to entity sets and entity sets to relationship sets.

Ellipses represent attributes

Double ellipses represent multivalued attributes. Dashed ellipses denote derived attributes.

Underline indicates primary key attributes (will study later)

### E-R Diagram With Composite, Multivalued, and Derived Attributes

### Constraints

We express cardinality constraints by drawing either a directed line ( $\rightarrow$ ), signifying “one,” or an undirected line (—), signifying “many,” between the relationship set and the entity set.

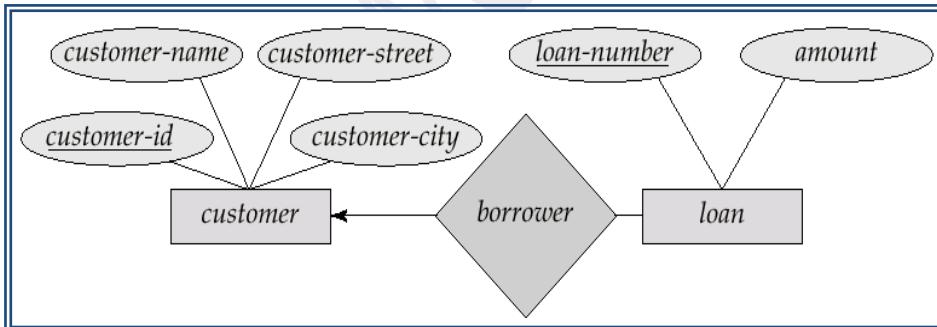

#### One-to-one relationship:

A customer is associated with at most one loan via the relationship *borrower*

A loan is associated with at most one customer via *borrower*

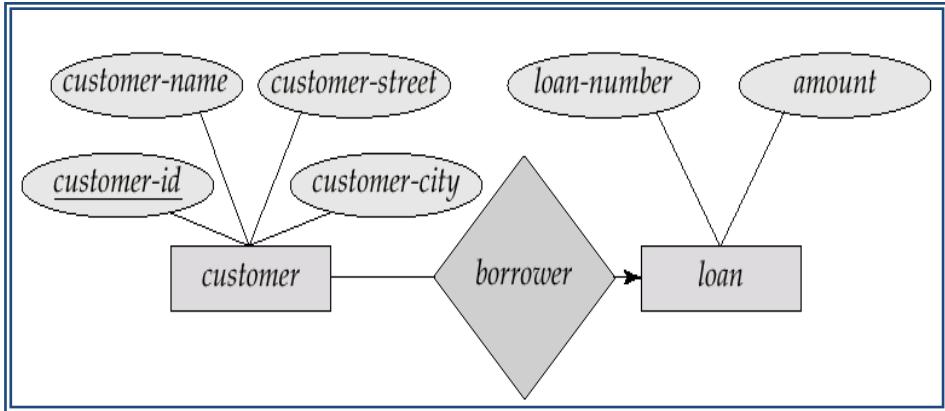

#### One-To-Many Relationship

In the one-to-many relationship, a loan is associated with at most one customer via *borrower*, and a customer is associated with several (including 0) loans via *borrower*

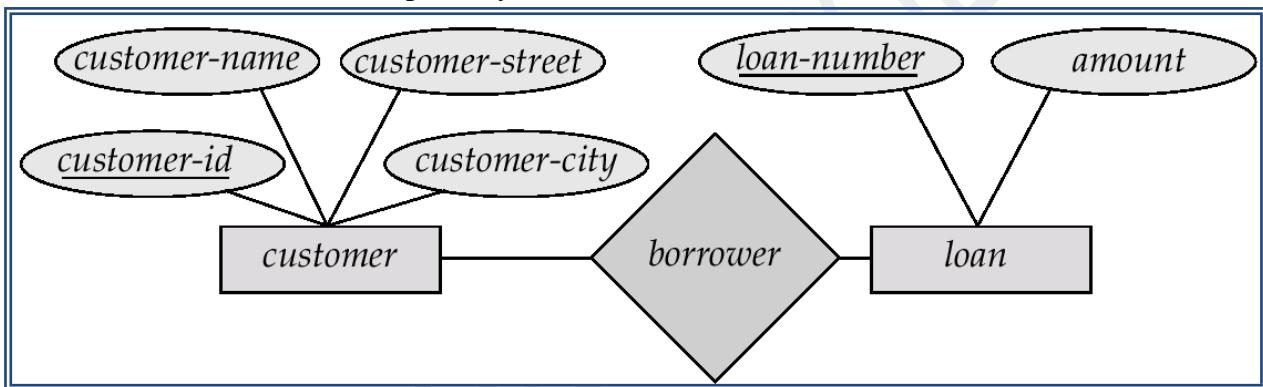

#### Many-To-One Relationships

In a many-to-one relationship, a loan is associated with several (including 0) customers via *borrower*, and a customer is associated with at most one loan via *borrower*

### Many-To-ManyRelationship

A customer is associated with several (possibly 0) loans via borrower. A loan is associated with several (possibly 0) customers via borrower.

### Design Issues

1. Use of entity sets vs. attributes
2. Choice mainly depends on the structure of the enterprise being modeled, and on the semantics associated with the attribute in question.
3. Use of entity sets vs. relationship sets  
Possible guideline is to designate a relationship set to describe an action that occurs between entities
4. Binary versus n-ary relationship sets
5. Although it is possible to replace any nonbinary ( $n$ -ary, for  $n > 2$ ) relationship set by a number of distinct binary relationship sets, an-ary relationship set shows more clearly that several entities participate in a single relationship.
6. Placement of relationship attributes

### Weak Entity Sets

- An entity set that does not have a primary key is referred to as a weak entity set.
- The existence of a weak entity set depends on the existence of a identifying entity set
  - it must relate to the identifying entity set via a total, one-to-many relationship set from the identifying to the weak entity set

- Identifying relationship depicted using a double diamond
- The discriminator (*or partial key*) of a weak entity set is the set of attributes that distinguishes among all the entities of a weak entity set.
- The primary key of a weak entity set is formed by the primary key of the strong entity set on which the weak entity set is existence dependent, plus the weak entity set's discriminator.

# Unit5

## Relational Database

### Design Features of good relational database

*branch=(branch\_name, branch\_city, assets)  
customer = (customer\_id, customer\_name, customer\_street,  
customer\_city)loan=(loan\_number, amount)  
account=(account\_number, balance)  
employee = (employee\_id, employee\_name, telephone\_number,  
start\_date)dependent\_name=(employee\_id, dname)  
account\_branch = (account\_number,  
branch\_name)loan\_branch = (loan\_number,  
branch\_name)borrower=(customer\_id,  
loan\_number)  
depositor = (customer\_id,  
account\_number)cust\_banker=(customer\_id, em  
ployee\_id, type)  
works\_for=(worker\_employee\_id, manager\_employee\_id)  
payment = (loan\_number, payment\_number, payment\_date,  
payment\_amount)savings\_account=(account\_number, interest\_rate)  
checking\_account= (account\_number, overdraft\_amount)*

## Atomic domains and First Normal Form

Domain is atomic if its elements are considered to be indivisible

unitsl Examples of non-atomic domains:

- ▶ Set of names, composite attributes
- ▶ Identification numbers like CS101 that can be broken up into parts

A relational schema R is in first normal form if the domains of all attributes of R are atomic. Non-atomic values complicate storage and encourage redundant (repeated) storage of data.

1. Example: Set of accounts stored with each customer, and set of owners stored with each account

2. We assume all relations are in first normal form (and revisit this in Chapter 9) Atomicity is actually a property of how the elements of the domain are used.

- 1 Example: Strings would normally be considered indivisible
- 2 Suppose that students are given roll numbers which are strings of the form CS0012 or EE1127
- 3 If the first two characters are extracted to find the department, the domain of roll numbers is not atomic.
- 4 Doing so is a bad idea: leads to encoding of information in application program rather than in the database.

## **DecompositionFunctionalDependencies**

1. Constraints on the set of legal relations.
2. Require that the value for a certain set of attributes determines uniquely the value for another set of attributes.
3. A functional dependency is a generalization of the notion of a *key*.

Let  $R$  be a relation schema

$$\alpha \subseteq R \text{ and } \beta \subseteq R$$

The functional dependency

$$\alpha \rightarrow \beta$$

holds on  $R$  if and only if for any legal relation  $r(R)$ , whenever any two tuples  $t_1$  and  $t_2$  of  $r$  agree on the attributes  $\alpha$ , they also agree on the attributes  $\beta$ . That is,

$$t_1[\alpha] = t_2[\alpha] \Rightarrow t_1[\beta] = t_2[\beta]$$

Example: Consider  $r(A, B)$  with the following instance of  $r$ .

On this instance,  $A \rightarrow B$  does NOT hold, but  $B \rightarrow A$  does hold.

Use of

## **Functional Dependencies theory**

We use functional dependencies to:

- 1 test relations to see if they are legal under a given set of functional dependencies.
  - If a relation  $r$  is legal under a set  $F$  of functional dependencies, we say that  $r$  satisfies  $F$ .
- 2 specify constraints on the set of legal relations
  - We say that  $F$  holds on  $R$  if all legal relations on  $R$  satisfy the set of functional dependencies  $F$ .

## **Using Multivalued Dependencies (MVDs)**

Let  $R$  be a relation schema and let  $\alpha \subseteq R$  and  $\beta \subseteq R$ . The multivalued dependency

$$\alpha \rightarrow\rightarrow \beta$$

holds on  $R$  if in any legal relation  $r(R)$ , for all pairs of tuples  $t_1$  and  $t_2$  in  $r$  such that  $t_1[\alpha] = t_2[\alpha]$ , there exist tuples  $t_3$  and  $t_4$  in  $r$  such that:

$$t_1[\alpha] = t_2[\alpha] = t_3[\alpha] = t_4[\alpha]$$

$$t_3[\beta] = t_1[\beta]$$

$$t_3[R-\beta] = t_2[R-\beta]$$

$$t_4[\beta] = t_2[\beta] t_4[R-$$

$$\beta] = t_1[R-\beta]$$

## **Use of Multivalued Dependencies**

→ We use multivalued dependencies in two ways:

1. To test relations to determine whether they are legal under a given set of functional and multivalued dependencies

2. To specify constraints on the set of legal relations. We shall thus concern ourselves *only* with relations that satisfy a given set of functional and multivalued dependencies.

→ If a relation  $r$  fails to satisfy a given multivalued dependency, we can construct a relation  $r'$  that does satisfy the multivalued dependency by adding tuples to  $r$ .

### Database Design Process

→ We have assumed schema  $R$  is given

1.  $R$  could have been generated when converting E-R diagram to a set of tables.  $R$  could have been a single relation containing *all* attributes that are of interest (called universal relation).
2. Normalization breaks  $R$  into smaller relations.  
 $R$  could have been the result of some ad hoc design of relations, which we then test/conver to normal form.
